Background

Today we will analyze some RNASeq data from Himes et al. on the effects of a common steroid (dexamethasone) on airway smooth muscle cells (ASM cells).

Our starting point is the "counts" data and "metadata" that contains the count values for each gene in their different experiment (i.e. cell lines with or without the drug).

Data Import

```
counts <- read.csv("airway_scaledcounts.csv", row.names=1)
metadata <-  read.csv("airway_metadata.csv")
```

Let's have a peak at these objects

```
head(counts)
```

```

```

Q1. How many genes are in this dataset?

```
nrow(counts)
```

```
[1] 38694
```

```
nrow(metadata)
```

```
[1] 8
```

Q. How many different experiments (col in counts or rows in metadata) are there?

```
ncol(counts)
```

```
[1] 8
```

Q2. How many 'control' cell lines do we have?

```
sum(metadata$dex == "control")
```

```
[1] 4
```

Toy differential gene expression

To start our analysis let's calculate the mean counts for all genes in the "control" experiments.

1. Extract all "control" columns from the `counts` objects
2. Calculate the mean 3-4. Do the same for "treated"
3. Compare these `control.mean`

```
control.inds <- metadata$dex == "control"
control.counts <- counts[ , control.inds]
```

```
control.means <- rowMeans(control.counts)
```

```
treated.inds <- metadata$dex == "treated"
treated.counts <- counts[ , treated.inds]
```

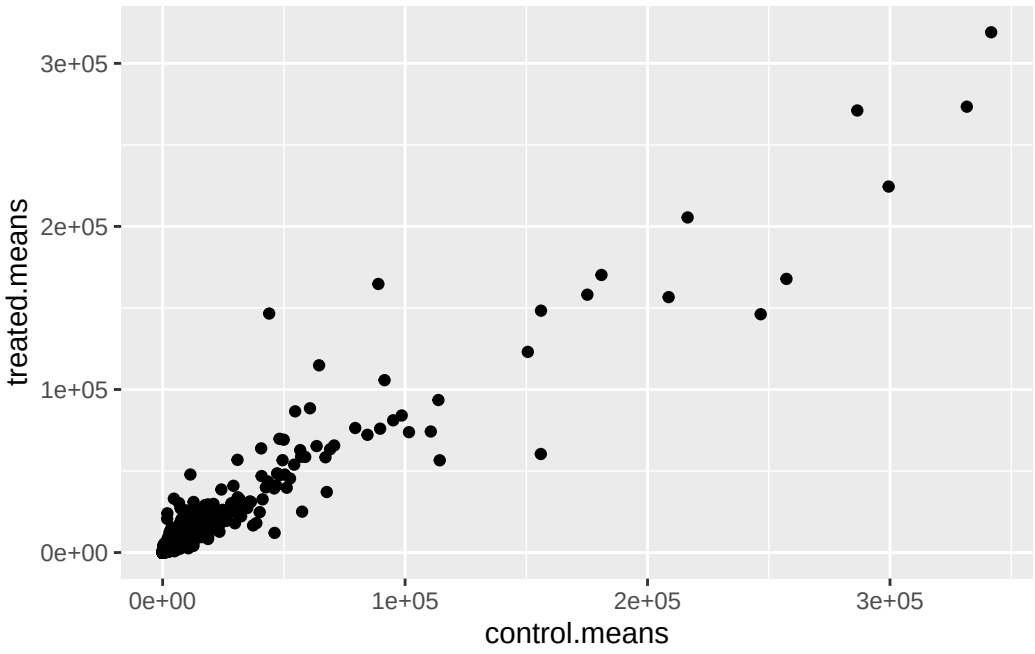
```
treated.means <- rowMeans(treated.counts)
```

Store these together for ease of bookkeeping as `meancounts`

```
meancounts <- data.frame(control.means, treated.means)
head(meancounts)
```

```
                control.means treated.means
ENSG00000000003        900.75        658.00
ENSG00000000005          0.00          0.00
ENSG00000000419        520.50        546.00
ENSG00000000457        339.75        316.50
ENSG00000000460         97.25         78.75
ENSG00000000938          0.75          0.00
```

```
library(ggplot2)
ggplot(meancounts) +
  aes(control.means, treated.means) +
  geom_point()
```

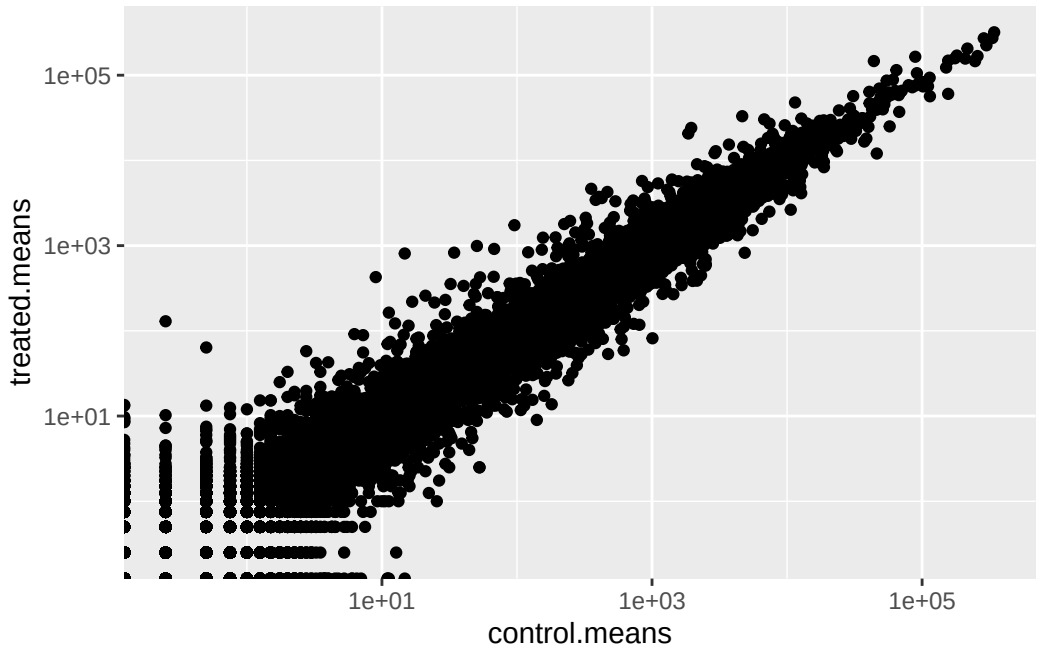


*if all points lie on the diagonal line, that means theres no difference between control and treated. Since the data is very skewed, we should start with a log transform.

```
ggplot(meancounts) +
  aes(control.means, treated.means) +
  geom_point() +
  scale_x_log10() +
  scale_y_log10()
```

```
Warning in scale_x_log10(): log-10 transformation introduced infinite values.
```

```
Warning in scale_y_log10(): log-10 transformation introduced infinite values.
```



We often talk about metrics like "log2 fold-change"

```
# treated/control

# log2() is easy for us to understand
# log2(10/10) = 0
# log2(10/20) = -1
# log2(10/40) = -2
# log2(40/10) = 2
```

Let's calculate the log2 fold change for our treated over control mean counts.

```
meancounts["log2fc"] <- log2(meancounts$treated.means / meancounts$control.means)
```

```
head(meancounts)
```

```
                control.means treated.means      log2fc
ENSG00000000003        900.75        658.00 -0.45303916
ENSG00000000005          0.00          0.00         NaN
ENSG00000000419        520.50        546.00  0.06900279
ENSG00000000457        339.75        316.50 -0.10226805
ENSG00000000460         97.25         78.75 -0.30441833
ENSG00000000938          0.75          0.00        -Inf
```

A common "rule of thumb" is a log2 fold change cutoff of +2 and -2 to call genes "up regulated" or "down regulated".

Number of "up" genes:

```
sum(meancounts$log2fc >= +2, na.rm=T)
```

```
[1] 1910
```

Number of "down" genes at -2 threshold:

```
sum(meancounts$log2fc <= -2, na.rm=T)
```

```
[1] 2330
```

DESeq2 analysis

Lets do this analysis properly – are the differences we see between drug and no drug significant given the replicate experiments.

```
library(DESeq2)
```

For DESeq analysis, we need three things:

1. count values (`countData`)
2. metadata telling us about the columns in `countData` (`colData`)
3. design of the experiment (i.e. what do you want to compare)

Our first function from DESeq2 will setup the input required for analysis by storing all these 3 things together.

```
dds <- DESeqDataSetFromMatrix(countData = counts,
                              colData = metadata,
                              design = ~dex)
```

```
converting counts to integer mode
```

```
Warning in DESeqDataSet(se, design = design, ignoreRank): some variables in
design formula are characters, converting to factors
```

The main function in DESeq2 that runs analysis is called `DESeq`

```
dds <- DESeq(dds)
```

```
estimating size factors
```

```
estimating dispersions
```

```
gene-wise dispersion estimates
```

```
mean-dispersion relationship
```

```
final dispersion estimates
```

```
fitting model and testing
```

```
res <- results(dds)
head(res)
```

```

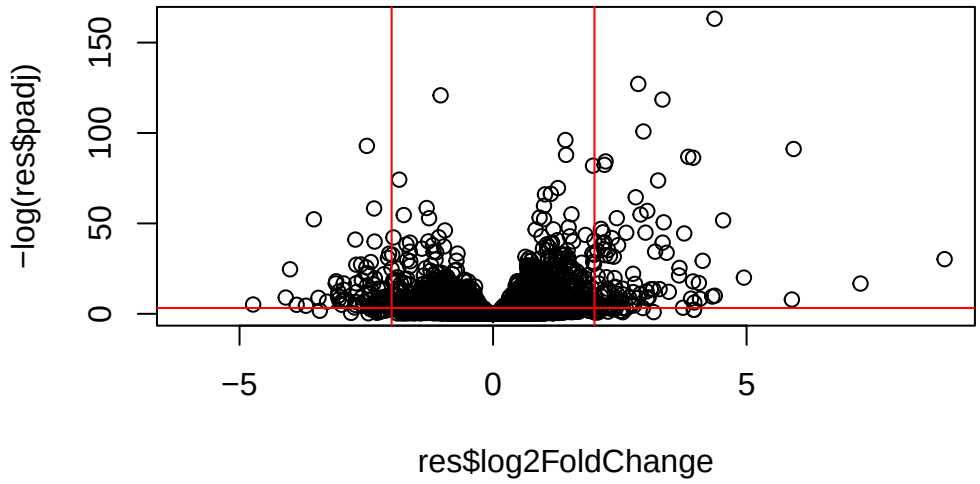
```

Volcano Plot

This is a common summary result figure from these types of experiments and plot the log2 fold-change vs. the adjusted p-value.

```
plot(res$log2FoldChange, -log(res$padj))
abline(v=c(-2,2), col="red") # ones that expression of genes w or w/o drug changes a lot (awa
abline(h=-log(0.04), col="red") # ones that are statistically significant (above the line)
```



Save our results

```
write.csv(res, file="my_results.csv")
```
